Abstract

With the China's civil aviation industry gradual market-oriented and the rapid development of China's economy, China's civil aviation transportation fuel consumption has grown significantly in nearly past three decades. Therefore, it's a very important strategic significance of the prediction of China's civil aviation transportation fuel consumption. In this paper, gray system and neural network approach, combined with China's civil aviation industry 1980-2010 total traffic volume of the data, we establish gray system GM (1,1) model and BP neural network model for civil aviation transport volume. Training and simulation of the back propagation neural network model and the gray system GM(1,1) used MATLAB. BP neural network modeling takes into account in three factors: the number of aircraft aviation industry, flight hours and total turnover. The fitting precision of the gray system GM(1,1) model is 64.2% while the fitting precision of the back propagation neural network model is 90.16%. Thus, the back propagation neural network model is better for estimating Civil aviation fuel consumption.

Key words: China's civil aviation industry; Fuel consumption; BP neural network; GM(1,1)

INTRODUCTION

China's civil aviation industry separate from the military jurisdiction and gradually return to the market since 1980, has more than 30 years. In three decades of market-oriented process, China's civil aviation industry has experienced rapid development. We can say that China's rapid economic development has effectively led the aviation industry. In this process, China's civil aviation industry has grown, the number and size of civil aviation enterprises expanding. There are six state-owned airlines in China's aviation industry, and it was 43 in the end of 2010. The categories include state-owned airlines, private airlines and joint venture airlines. At the same time, China's civil aviation industry fuel consumption is also increasing. Therefore, the aviation fuel consumption forecast is even more important.

Fuel consumption in itself is a non-linear, complex and open system, is the result of interaction of many factors. Some factors, such as political and economic factors, and some unexpected events (such as natural disasters, disease and terrorist attacks, etc.) and other factors. Because of the unpredictable nature of these factors, or the absence of such information, while the predictive modeling work to bring a certain degree of difficulty, which affects the prediction accuracy of the results.

Grey prediction method is the 1980s Professor Deng Julong gray system theory proposed prediction method. For the information is incomplete or imperfect situation has good applicability. One single sequence of first-order GM (1,1) dynamic model has fewer samples, modeling and simple, widely used in the country. BP (back propagation) neural network is Rumelhart and McClelland 1986 by a team of scientists led by proposed is a method of error back propagation algorithm to train multi-layer feedforward neural networks, is currently the most widely used one neural network model. BP neural network can learn and store a large number of input - output mode mappings without prior description of this mapping

reveals the mathematical equations. BP neural network with non-linear, parallel distributed processing, self-learning, self-organizing, adaptive, etc., can accurately simulate the real demand for aviation fuel.

In this paper, China's civil aviation 1980-2010 fuel consumption data for 31 years, the use of gray system and neural network approach to build China's civil aviation fuel consumption of Grey System GM (1,1) model and BP neural network model. Study fuel consumption prediction method can predict the future of aviation fuel consumption for business decisions and provide reference for government policy makers to realize the sustainable development of civil aviation.

1. DATA

According to the China Air Transport statistics from published annually by the Civil Aviation Authority, we get from 1980 to 2010 aviation fuel consumption data from the "Statistical data on Civil Aviation of China 2010."

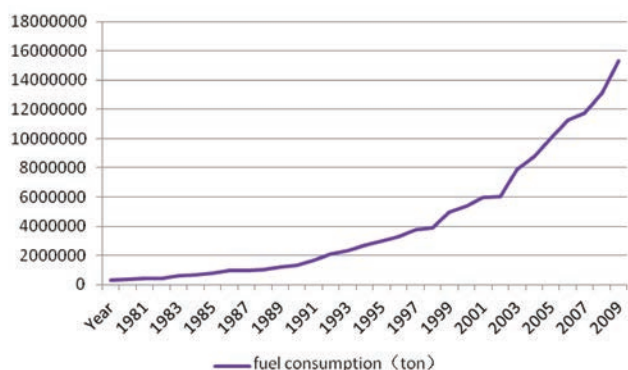

Figure 1
1980-2010 China's Civil Aviation Transportation Fuel Consumption

2. GREY SYSTEM GM (1,1) MODEL

The fuel consumption of China's civil aviation transportation from 1980 to 2010 as GM (1,1) model of the original series $x^{(0)}$. Forecast 2011-2020 total turnover. Modeling process includes generating a cumulative sequence, using the mean cumulative number of solved column parameters using the least square method for solving gray, gray parameters into the differential equations for modeling and prediction of the original sequence.

$$x^{(0)} = (x^{(0)}(1), x^{(0)}(2), \dots, x^{(0)}(n)) \tag{1}$$

Where n represents the number of samples of the original series, Here $n=31$.

1 number of times as cumulative is:

$$x^{(1)} = (x^{(1)}(1), x^{(1)}(2), \dots, x^{(1)}(n)) \tag{2}$$

and

$$x^{(1)}(1) = x^{(0)}(1)$$

$$x^{(1)}(k) = x^{(1)}(k-1) + x^{(0)}(k)$$

Mean number listed is:

$$z^{(1)} = (z^{(1)}(1), z^{(1)}(2), \dots, z^{(1)}(n-1)) \tag{3}$$

and

$$z^{(1)}(k) = 0.5x^{(0)}(k) + 0.5x^{(0)}(k+1)$$

Whitening system differential equations is:

$$\frac{dx^{(1)}}{dt} + ax^{(1)} = d \tag{4}$$

Its time response function that is the solution of the differential equation is:

$$\hat{x}^{(1)}(k+1) = (x^{(0)}(1) - u/a)e^{-ak} + u/a \tag{5}$$

The solution to restore the original sequence simulation solution:

$$\hat{x}^{(0)}(k+1) = (1 - e^{-a})(x^{(0)}(1) - u/a)e^{-ak} \tag{6}$$

The gray parameters (a, u) which obtained by least squares method, using the equation is:

$$\begin{bmatrix} a \\ u \end{bmatrix} = (B^T B)^{-1} B^T Y_n \tag{7}$$

and

$$B = \begin{bmatrix} -z^{(1)}(1) & 1 \\ -z^{(1)}(2) & 1 \\ \vdots & \vdots \\ -z^{(1)}(n-1) & 1 \end{bmatrix}$$

$$Y_n = [x^{(0)}(2), x^{(0)}(3), \dots, x^{(0)}(n)]^T$$

Meanwhile calculation model accuracy, which is calculated as:

$$s = 1 - \frac{1}{N} \sum_{i=1}^N \frac{|t_i - \hat{t}_i|}{t_i} \times 100\% \tag{8}$$

Wherein s represents the model accuracy, the number of samples N , t_i is a sample value (actual value) of t_i analog values.

3. BP NEURAL NETWORK MODELING

BP neural network is a multilayer feedforward neural networks, the topology consists of three layers: the input layer, hidden layer and output layer.

Figure 2
Multi-Layer Structure of A Neural Network

We make the fuel consumption as the output vectors, and the number of aircraft, flight hours, with a total turnover and airline mileage and other four factors be the impact on fuel consumption input vector. While the dimension difference exists input and output vectors are standardized, so that they have zero mean and a standard deviation of unity.

Here, we choose to contain a hidden layer of BP neural network. Nodes in the input layer dimension of

the input vectors determined input vector dimension is 4, so the input layer nodes identified as 4. Output layer nodes have determined the dimension of input vectors, where the output nodes is 1. Hidden layer node selection currently no theoretical guidance, too much will increase the network node network training time, will reduce the generalization ability of the network; But too little network nodes cannot effectively learn the training samples, modeling insufficient. Hidden layer nodes can refer to the following formula:

$$h = (m + n)^{\frac{1}{2}} + a \quad (9)$$

of which: number of nodes in the hidden layer, the input layer nodes for the output layer nodes, is an integer between 1 and 10. According to equation (9) hidden layer nodes initially identified through repeated training, and finally determine the hidden layer nodes is 8. Thus forming a 4-8-1 BP neural network.

The sample data from 1980 to 2000 as the training sample set 2001-2006 2010 sample data as the test sample set. Using Matlab software for data programming and analysis. While the use of the test sample data to test the model.

True Values and Simulated Comparison

CONCLUSION

In this paper, we use gray system GM (1,1) model and BP neural network model for 1980-2010 China's civil aviation industry aviation fuel consumption simulation study. The results showed that: BP neural network model has a strong self-organizing, self-learning, adaptive capacity, superior gray system GM (1,1) model is better suited for the civil aviation industry aviation fuel consumption prediction. BP neural network model can be used in the future China's civil aviation industry development trend of aviation fuel consumption forecasts for government policy makers to provide a reference.
